Figure 3.20: Resolution Strategy implementation

Transient mode: 11.10

- ► Retry—number of retries.
- ► Time interval—time between the retries (should not be very long).
- ► Unit for internal—unit of measurement for time interval (minutes or hours).
- ► Rollover—time difference between the retries (linear or exponential).

Persistent mode:

- ► Resubmission group—period in which the system executes automated retries.
- ► Retry mode—determines if users are allowed to execute the

repeat option manually, or only in the automated mode.

▶ Confirm mode—similar to the <mark>retry</mark> mode, determines if users are allowed to execute the confirm option manually, or only in the automated mode.

▶ Discard mode—similar to the <mark>retry</mark> mode, determines if users are allowed to execute the discard option manually or only in the automated mode.

▶ Residence time—defined as the interval during which it's possible to use the repeat button in the manual mode. After that time, it's only possible to use the confirm and the discard options.

▶ Unit—residence time—unit of measurement residence time.

After setting up the Resolution Strategy, make sure that it's saved and activated and you can use it to manage Postprocessing Office errors in automated mode which can simplify the monitoring of a SOA integration scenarios.
